TP7 Event-driven Micro-Service Pattern: CQRS & Event Sourcing

Soit une application micro-Service (voir **figure 1**)) qui est constituée de deux micro-services *Ms-Library* et *Ms-Editeur*. On souhaite ajouter une fonctionnalité qui affiche pour chaque Chambre son statut → *Chambre-Status*(*idCh*, *idH*, *nbReservation*).

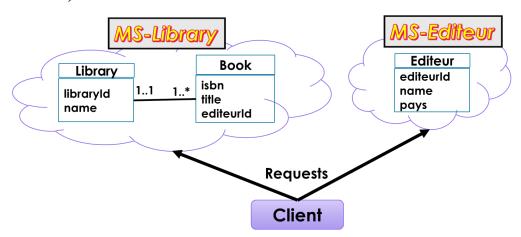

Figure 1. Application Microservice sans CQRS

1. Core-Api:

- a. Commads: LibrayCreationCommand, AddBookCommand, RemoveBookCommand, EditeurCreationCommand
- b. Events: LibraryCreatedEvent, BookAddedEvent, BookRemovedEvent, EditeurCreatedEvent
- c. DTO: LibraryDTO, BookDTO, EditeurDTO

2. Lab1: Separate Command and Query Services (Voir Figure 2)

- a. Ms-Command-Library: Ce micro service gère un Aggregate Root LibraryAggregate (without state storage).
 - i. LibraryAggregate: Not Null [LibraryId, name, isbn], Unique [For each Library the isbn must be unique].
- b. Ms-Query-Library: Ce microservice gére la partie Query en mette à jour deux entités : Library et Book en se basant sur les évènements envoyés par la partie Command : Ms-Command-Library.
 - i. Entity, Repository, Projection
 - ii. BDD: jdbc:mysql://localhost:3306/Query-Bdd

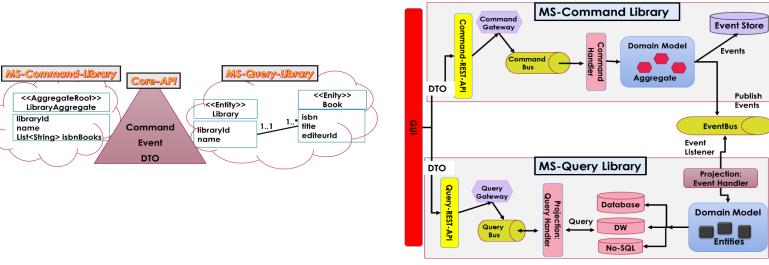

Figure 2. Lab 1: Separate Command & Query Services

- 3. Lab2: Materialize join & State stored aggregate (Voir Figure 3)
 - a. **Ms-Command-Editeur:** Ce micro service gère un **state Stored Aggregate** (i.e., Entity/Aggregate) EditeurAggregate
 - i. State Stored Aggregate, Repository, Projection et Command Controller.
 - ii. BDD: jdbc:mysql://localhost:3306/Editeur-bdd
 - b. Ms-Command-Library-Book: Ce micro service gère deux Aggregates: un Aggregate Root Library, et un Aggregate Member Book.
 - i. Library & Book: Not Null [LibraryId, name, isbn, Title], Unique [For each Library the isbn must be unique].
 - c. **Ms-Query-Library:** Ce micro service gère la **materialized-Join** *EditeurJoinBook* en mettant à jour cette dernière en fonction des événements publiés (*EditeurCreatedEvent*, *BookAddedEvent* et *BookRemoveEvent*).
 - i. Entity, Repository, Projection
 - ii. BDD: jdbc:mysql://localhost:3306/Join-Query-Bdd

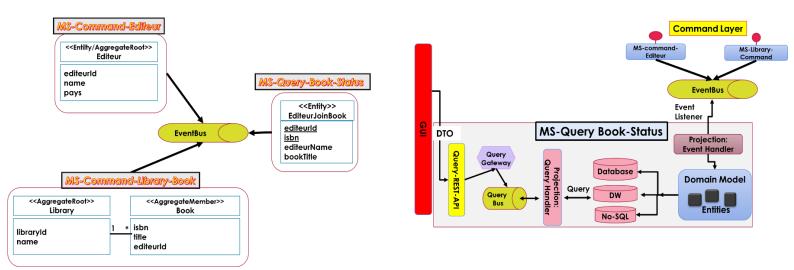

Figure 3. Lab 2: Materialize join & State stored aggregate

- 4. Lab3: State stored & Materialized Join with MongoDB (Voir Figure 4)
 - a. Ms-Command-Library-Book-Stored: Ce micro service gère deux state-stored Aggregates: un Entity/Aggregate-Root Library, et un Entity/Aggregate Member Book.
 - i. Library & Book: Not Null [LibraryId, name, isbn, Title], Unique [For each Library the isbn must be unique].
 - ii. State Stored Aggregate, Repository, Projection et Command Controller.
 - iii. BDD: jdbc:mysql://localhost:3306/tp-cqrs-stored
 - b. *Ms-Query-Join-Library-Book:* Ce micro service gère la materialized-Join *JoinTable* en mettant à jour cette dernière en fonction des événements publiés (*LibraryCreatedEvent*, *BookAddedEvent* et *BookRemoveEvent*).
 - i. MongoDb Document, MongoRepository, Projection
 - ii. BDD: mongodb://localhost:27017 & database=join-library-book
